Introduction

This guide provides information about deploying Dell PowerVault MD MD3600i and MD3620i storage arrays. The deployment process includes:

- Hardware installation
- Modular Disk Storage Manager (MDSM) software installation
- Initial system configuration

Other information provided include system requirements, storage array organization, and utilities.

NOTE: For more information on product documentation, see support.dell.com/manuals.

MDSM enables an administrator to configure and monitor storage arrays for optimum usability. The version of MDSM included on the MD3600i Series resource media can be used to manage both the MD3600i Series and the earlier generation MD3200i and MD3000i Series storage arrays. MDSM is compatible with both Microsoft Windows and Linux operating systems.

System Requirements

Before installing and configuring the MD3600i Series hardware and software, ensure that the minimum system requirements are met, and the supported operating system is installed. For more information, see the Dell PowerVault Support Matrix available on support.dell.com/manuals.

Management Station Requirements

A management station uses MDSM to configure and manage storage arrays across the network, and must meet the following minimum system requirements:

- Intel Pentium or an equivalent processor (333 MHz or faster) with 512 MB RAM (1024 MB recommended)
- 1 GB disk space
- Display resolution of 1024x768 with 16 million colors (1280x1024 32-bit recommended)
• Microsoft Windows, Red Hat Enterprise Linux, and SUSE Linux
  Enterprise Server. Operating system installations can be either native or
  hypervisor guest configurations. Supported hypervisors include Microsoft
  Hyper-V, Citrix XenServer, and VMware. For information about the
  supported versions, see the Support Matrix at support.dell.com.
• Administrator or equivalent permissions.

Introduction to Storage Arrays

A storage array includes various hardware components, such as physical disks,
RAID controller modules, fans, and power supplies, gathered into enclosures.
An enclosure containing physical disks accessed through RAID controller
modules is called a storage array.

One or more host servers attached to the storage array can access the data on
the storage array. You can also establish multiple physical paths between the
host(s) and the storage array so that loss of any single path (for example,
through failure of a host server port) does not result in loss of access to data
on the storage array.

The storage array is managed by MDSM running on a:
• Host server—On a host server, MDSM and the storage array communicate
  management requests and event information using iSCSI ports.
• Management station—On a management station, MDSM communicates
  with the storage array either through an Ethernet connection to the
  storage array management port or though an Ethernet connection to a
  host server, which passes management information between the
  management station and the storage array using iSCSI ports.

Using MDSM, you can configure the physical disks in the storage array into
logical components called disk groups and then divide the disk groups into
virtual disks. Disk groups are created in the unconfigured capacity of a storage
array. Virtual disks are created in the free capacity of a disk group.

Unconfigured capacity comprises physical disks not already assigned to a disk
group. When a virtual disk is created using unconfigured capacity, a disk
group is automatically created. If the only virtual disk in a disk group is
deleted, the disk group is also deleted. Free capacity is space in a disk group
that is not assigned to any virtual disk.
Data is written to the physical disks in the storage array using RAID technology. RAID levels define the way in which data is written to physical disks. Different RAID levels offer different levels of accessibility, redundancy, and capacity. You can set a specified RAID level for each disk group and virtual disk on your storage array.

For more information about using RAID and managing data in your storage solution, see the *Owner’s Manual* at [support.dell.com/manuals].
Hardware Installation

Before using this guide, ensure that you review the instructions in the:

• *Getting Started Guide*—The *Getting Started Guide* that shipped with the storage array provides information to configure the initial setup of the system.

• Planning section of the *Owner’s Manual*—The planning section provides information about important concepts you should know before setting up your storage solution at [support.dell.com/manuals](http://support.dell.com/manuals).

Storage Configuration Planning

Consider the following before installing your storage array:

• Evaluate data storage needs and administrative requirements.

• Calculate availability requirements.

• Decide the frequency and level of backups, such as weekly full backups with daily partial backups.

• Consider storage array options, such as password protection and e-mail alert notifications for error conditions.

• Design the configuration of virtual disks and disk groups according to a data organization plan. For example, use one virtual disk for inventory, a second for financial and tax information, and a third for customer information.

• Decide whether to allow space for hot spares, which automatically replace failed physical disks.
About the Storage Array Connections

The storage array is connected to a host using two hot-swappable RAID controller modules. The RAID controller modules are identified as RAID controller module 0 and RAID controller module 1.

Each RAID controller module has two iSCSI In port connectors that provide Ethernet connections to the host server or switches. Each RAID controller module also contains an Ethernet management port and a SAS Out port. The Ethernet management port allows you to install a dedicated management station (server or stand-alone system). The SAS Out port allows you to connect the storage array to optional PowerVault MD1200 Series expansion enclosures for additional storage capacity.

Each PowerVault MD3600i Series storage array can be expanded to a maximum of 96 physical disks through a maximum of seven MD1200 Series expansion enclosures.

Cabling the Storage Array

The iSCSI interface enables different host-to-controller configurations. The figures in this chapter are grouped according to the following categories:

- Direct-attached configurations (no Ethernet switches are used)
- Network-attached (SAN) configurations (Ethernet switches are used)

Redundant and Non-Redundant Configurations

Non-redundant configurations are configurations that provide only a single data path from a host to the storage array. This type of configuration is only recommended for non-critical data storage. Path failure from a failed or removed cable, a failed NIC, or a failed or removed RAID controller module results in loss of host access to storage on the storage array.

Redundancy is established by installing separate data paths between the host and the storage array, in which each path is to one of the two RAID controller modules installed in the storage array. Redundancy protects the host from losing access to data in the event of path failure, because both RAID controller modules can access all the disks in the storage array.
Direct-Attached Configurations
You can connect the Ethernet ports of the host servers directly to the storage array RAID controller module iSCSI ports.

Single Path Data Configurations
With a single path configuration, a group of heterogeneous hosts can be connected to the storage array through a single physical Ethernet port. Since there is only one port, there is no redundancy, although each iSCSI portal supports multiple connections. This configuration is supported for both single controller and dual controller modes.
Figure 2-1 shows a non-redundant cabling configuration to the RAID controller modules using a single path data configuration.

**Figure 2-1. Two Hosts Connected to a Single Controller**
Figure 2-2 shows one host connected to a single controller array.

Figure 2-2. One Host Connected to a Single Controller
Figure 2-3 shows four stand-alone hosts supported in a dual controller array configuration with a single data path.

**Figure 2-3. Four Hosts in a Dual-Controller Configuration**
Dual-Path Data Configuration

In Figure 2-4, up to two servers are directly attached to the RAID controller modules. If the host server has a second Ethernet connection to the array, it can be attached to the iSCSI ports on the array's second controller. This configuration provides improved availability by allowing two separate physical paths for each host, which ensures full redundancy if one of the paths fail.

In Figure 2-5, up to two cluster nodes are directly attached to two RAID controller modules. Since each cluster node has redundant paths, loss of a single path would still allow access to the storage array through the alternate path.

IP: 192.168.130.102/24
Network-Attached Configurations

You can also cable the host servers to the RAID controller module iSCSI ports through industry-standard 10G or 1G Ethernet switches. An iSCSI configuration that uses Ethernet switches is frequently referred to as an IP SAN. By using an IP SAN, the PowerVault MD3600i Series storage array can support up to 64 hosts simultaneously. This configuration supports either single- or dual-path data configurations and either single or dual controller modules.

Figure 2-6 shows up to 64 stand-alone servers attached (using multiple sessions) to a single RAID controller module through a network. Hosts that have a second Ethernet connection to the network allow two separate physical paths for each host, which ensures full redundancy if one of the paths fails. It is recommended you use two switches for more redundancy. However, single switch configuration is also supported. Figure 2-7 shows how the same number of hosts can be similarly attached to a dual RAID controller module configuration.

Figure 2-8 shows up to 64 stand-alone servers attached (using multiple sessions) to a single RAID controller module through a network using a 1G to 10G aggregation scheme. The NICs on the servers are 1G NICs and the uplink ports on the 1G switches are 10G. Hosts that have a second Ethernet connection to the network allow two separate physical paths for each host, which ensures full redundancy if one of the paths fails. It is recommended you use two switches for more redundancy. However, single switch configuration is also supported.

Figure 2-9 shows how the same number of hosts can be similarly attached to a dual RAID controller module configuration. Hardware redundancy is achieved in this configuration, in case of any switch failure.

Cabling PowerVault MD1200 Series Expansion Enclosures

You can expand the capacity of your PowerVault MD3600i Series storage array by adding PowerVault MD1200 Series expansion enclosures. You can expand the physical disk pool to a maximum of 96 physical disks using a maximum of seven expansion enclosures.

Expanding With Previously Configured PowerVault MD1200 Series Expansion Enclosures

Use this procedure if your expansion enclosure is directly attached to and configured on a Dell PERC H800 adapter. Data from virtual disks created on a PERC H800 adapter cannot be directly migrated to a PowerVault MD3600i Series storage array or to a PowerVault MD1200 Series expansion enclosure connected to a PowerVault MD3600i Series storage array.

⚠️ CAUTION: If a PowerVault MD1200 Series expansion enclosure that was previously attached to PERC H800 adapter is used as an expansion enclosure to a PowerVault MD3600i Series storage array, the physical disks of the expansion enclosure are reinitialized and data is lost. You must backup all data on the expansion enclosure before attempting the expansion.

To attach previously configured PowerVault MD1200 Series expansion enclosures to the PowerVault MD3600i Series storage array:

1. Back up all data on the expansion enclosure(s).

2. While the enclosure is still attached to the PERC H800 controller, upgrade the expansion enclosure firmware to the latest version at support.dell.com.
   
   Windows systems users can reference the DUP.exe package and Linux kernel users can reference the DUP.bin package.
3 Before adding the expansion enclosure(s), ensure that the storage array software is installed and is up to date. For more information, see the Support Matrix at support.dell.com/manuals.
   a Install the software and driver package included on the PowerVault MD3600i Series resource media. For information about installing the software, see "Software Installation" on page 29.
   b Using MDSM, update the RAID controller module firmware and NVSRAM to the latest versions available at support.dell.com. In the Enterprise Management Window (EMW), Click Tools→Upgrade RAID Controller Module Firmware.

4 Stop all I/O and turn off the system.
   a Stop all I/O to the storage array and turn off the host systems attached to the storage array.
   b Turn off the storage array.
   c Turn off the expansion enclosure(s) in the affected system.

5 Cable the expansion enclosure(s) to the storage array.

6 Turn on attached units:
   a Turn on the expansion enclosure(s). Wait for the enclosure status LED to light blue.
   b Turn on the storage array and wait for the status LED to indicate that the unit is ready:
      • If the status LEDs light solid amber, the storage array is still coming online.
      • If the status LEDs are blinking amber, there is an error that can be viewed using the MDSM.
      • If the status LEDs light solid blue, the storage array is ready.
   c After the storage array is online and ready, turn on any attached host systems.

7 After the PowerVault MD1200 Series expansion enclosure is configured as an expansion enclosure of the storage array, restore the data that was backed up in step 1.

After the expansion enclosures are online, they can be accessed as a part of the storage array.
Expanding With New PowerVault MD1200 Series Expansion Enclosures

Perform the following steps to attach new PowerVault MD1200 Series expansion enclosures to a PowerVault MD3600i Series storage array:

1. Before adding the expansion enclosure(s), ensure that the storage array software is installed and up to date. For more information, see the Support Matrix at support.dell.com/manuals.
   
   a. Install the software and driver package included on the PowerVault MD3600i Series resource media.
   
   b. Set up the MD1200 Series expansion enclosure(s). For information about setting up the MD1200 Series expansion enclosure(s), see the Hardware Owner’s Manual at support.dell.com/manuals.
   
   c. Using MDSM, update the RAID controller module firmware and NVSRAM to the latest versions available on support.dell.com. From the Enterprise Management Window (EMW), Click Tools→Upgrade RAID Controller Module Firmware.

2. Stop I/O and turn off all systems:
   
   a. Stop all I/O to the storage array and turn off affected host systems attached to the storage array.
   
   b. Turn off the storage array.
   
   c. Turn off any expansion enclosure(s) in the affected system.

3. Cable the expansion enclosure(s) to the storage array.

4. Turn on attached units:
   
   a. Turn on the expansion enclosure(s). Wait for the enclosure status LED to light blue.
   
   b. Turn on the storage array and wait for the status LED to indicate that the unit is ready:
      
      • If the status LEDs light solid amber, the storage array is still coming online.
      
      • If the status LEDs are blinking amber, there is an error that can be viewed using MDSM.
      
      • If the status LEDs light solid blue, the storage array is ready.
   
   c. After the storage array is online and ready, turn on any attached host systems.
5 Using MDSM, update all attached expansion enclosure firmware if it is out of date:
   a From the EMW, select the enclosure that you want to update and enter the Array Management Window (AMW). Click Advanced→Maintenance→Download→EMM Firmware.
   b Select Select All to update all the attached expansion enclosures simultaneously.
Software Installation

The Dell PowerVault MD3600i Series resource media contains software and drivers for both Linux and Microsoft Windows operating systems.

The root of the media contains a **readme.txt** file covering changes to the software, updates, fixes, patches, and other important data applicable to both Linux and Windows operating systems. The **readme.txt** file also specifies requirements for accessing documentation, information regarding versions of the software on the media, and system requirements for running the software.

For more information on supported hardware and software for Dell PowerVault systems, see the Support Matrix at [support.dell.com/manuals](http://support.dell.com/manuals).

**NOTE:** It is recommended that you install all the latest updates available at [support.dell.com](http://support.dell.com).

Installing MD Storage Software

The PowerVault MD3600i Series storage software installer provides features that include the core software, providers, and optional utilities. The core software feature includes the host-based storage agent, multipath driver, and Modular Disk Storage Manager (MDSM) application used to configure, manage, and monitor the storage array solution. The providers feature includes providers for the Microsoft Virtual Disk Service (VDS) and Microsoft Volume Shadow-Copy Service (VSS) framework. The Modular Disk Configuration Utility (MDCU) is an optional utility that provides a consolidated approach for configuring the management ports, iSCSI host ports, and creating sessions for the iSCSI Modular Disk storage arrays. It is recommended that you install and use the MDCU to configure iSCSI on each host connected to the storage array.

**NOTE:** For more information about the Microsoft VDS and Microsoft VSS providers, see the MD3600i Owner's Manual. To install the software on a Windows or Linux system, you must have administrative or root privileges.
NOTE: If Dynamic Host Configuration Protocol (DHCP) is not used, initial configuration of the management station must be performed on the same physical subnet as the storage array. Additionally, during initial configuration, at least one network adapter must be configured on the same IP subnet as the storage array's default management port (192.168.128.101 or 192.168.128.102). After initial configuration, the management ports are configured using MDSM and the management station's IP address can be changed back to the previous settings.

The PowerVault MD3600i Series resource media provided offers the following three installation methods:

• Graphical Installation (Recommended)—This is the recommended installation procedure for most users. The installer presents a graphical wizard-driven interface that allows customization of which components are installed.

• Console Installation—This installation procedure is useful for Linux users that do not desire to install an X-Window environment on their supported Linux platform.

• Silent Installation—This installation procedure is useful for users that prefer to create scripted installations.

Graphical Installation (Recommended)

Depending on your configuration, insert the resource media in either the management station or the host server.

Depending on the autorun settings of the operating system, the Dell PowerVault MD36xxi Resource DVD window may be displayed or a prompt may be displayed to run the md_launcher.exe file. If the PowerVault MD launcher is not displayed and there is no prompt to run the md_launcher.exe file, perform the following steps:

• For Windows-based systems, navigate to the root of the resource media and run the md_launcher.exe file.

• For Linux-based systems, navigate to the root of the resource media and run the autorun file.

NOTE: By default, Red Hat Enterprise Linux (RHEL) mounts the resource media with the –noexec mount option which does not allow you to run executable files. For more information and to change the settings, see “Release Notes” in the Readme.txt file. The Readme.txt file is located in the root of the resource media.
2 Select Install MD36xxi Storage Software.

3 Install the MD Storage Manager software. Select one of the following installation options:
   • **Full (recommended)**—This package installs core software, providers, and utilities. It includes the necessary host-based storage agent, multipath driver, MD Storage Manager, providers, and optional utilities.
   • **Host Only**—This package includes the host-based storage agent, multipath drivers, and optional utilities required to configure the host.
   • **Management Station**—This package includes the MD Storage Manager, providers, and optional utilities.
   • **Custom**—This option allows you to select specific components.

4 Reboot each host server.

5 Launch the MDCU if it does not appear automatically after rebooting the host server. To launch the MDCU:
   • In a Windows-based operating system, click Start → Dell → Modular Disk Configuration Utility.
   • In a Linux-based operating system, double-click the Modular Disk Configuration Utility icon on the desktop.

6 Follow the instructions on the screen and proceed to the next step.

7 Start the **Modular Disk Storage Manager Client** and discover the array(s).

8 Perform the remaining post-installation tasks.

**NOTE:** The installer automatically installs the required drivers, initiators, and operating system patches/hotfixes. All the drivers are also available at support.dell.com.
Console Installation

**NOTE:** Console installation only applies to Linux systems that are not running a graphical environment.

The autorun script in the root of the resource media detects when there is no graphical environment running and automatically starts the installer in a text-based mode. This mode provides the same options as graphical installation with the exception of the MDCU specific options. The MDCU requires a graphical environment to operate.

**NOTE:** The console mode installer provides the option to install the MDCU. However, a graphical environment is required to utilize the MDCU.

Silent Installation

This option allows you to install the software in an unattended mode. To run silent installation in a Windows system, perform the following steps:

1. To begin the installation with all the default options, navigate to the windows folder on the resource media and run the following command:
   
   ```bash
   md36xxi_install -i silent
   ```

2. To specify which features are to be installed silently, modify the `custom_silent.properties` file located in the same directory and copy it to a writable location on the host server. This file contains a list of supported features and their descriptions. To utilize the modified `custom_silent.properties` file, run the command:

   ```bash
   md36xxi_install -f C:\path\to\custom_silent.properties
   ```
To run silent installation in a Linux system, perform the following steps:

1. To begin the installation with all the default options, navigate to the linux folder on the resource media and run the following command:
   
   ```bash
   ./md36xxi_install.bin   -i silent
   ```

2. To specify which features are to be installed silently, you must modify the custom_silent.properties file located in the same directory and copy it to a writable location on the host server. This file contains a list of supported features and their descriptions. To utilize the modified custom_silent.properties file, run the command:

   ```bash
   ./md36xxi_install.bin   -f /path/to/custom_silent.properties
   ```
Post Installation Tasks

Before using the storage array for the first time, complete a number of initial configuration tasks in the order shown. These tasks are performed using the MD Storage Manager (MDSM) or, optionally, the Modular Disk Configuration Utility (MDCU) software.

**NOTE:** If Dynamic Host Configuration Protocol (DHCP) is not used, perform the initial configuration using the management station on the same physical subnet as the storage array. Additionally, during initial configuration, at least one network adapter must be configured on the same IP subnet as the storage array’s default management port (192.168.128.101 or 192.168.128.102). After initial configuration, the management ports are configured using MDSM and the management station’s IP address can be changed back to the previous settings.

**Before You Begin**

Before you begin configuring iSCSI, fill out the iSCSI configuration worksheet. Gathering this type of information about your network prior to starting the configuration steps helps you to complete the process in less time.

**iSCSI Configuration Terminology**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAP (Challenge Handshake Authentication Protocol)</td>
<td>An optional security protocol used to control access to an iSCSI storage system by restricting use of the iSCSI data ports on both the host server and storage array. For more information on the types of CHAP authentication supported, see &quot;Understanding CHAP Authentication&quot; on page 66.</td>
</tr>
<tr>
<td>Host or host server</td>
<td>A server connected to the storage array using iSCSI ports.</td>
</tr>
<tr>
<td>Host server port</td>
<td>SCSI port on the host server used to connect it to the storage array.</td>
</tr>
</tbody>
</table>
Table 4-1. Standard Terminology Used in iSCSI Configuration

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>iSCSI initiator</td>
<td>The iSCSI-specific software installed on the host server that controls communications between the host server and the storage array.</td>
</tr>
<tr>
<td>iSCSI host port</td>
<td>The iSCSI port (two per controller) on the storage array.</td>
</tr>
<tr>
<td>iSNS (Microsoft Internet Storage Naming Service)</td>
<td>An automated discovery, management and configuration Storage Naming Service tool used by some iSCSI devices.</td>
</tr>
<tr>
<td>Management station</td>
<td>The system from which you manage your host server/storage array configuration.</td>
</tr>
<tr>
<td>Storage array</td>
<td>The enclosure containing the storage data accessed by the host server.</td>
</tr>

<td>Target</td>
<td>An iSCSI port on the storage array that accepts and responds to requests from the iSCSI initiator installed on the host server.</td>
</tr>
</tbody>
</table>

**iSCSI Configuration Worksheet**

The iSCSI configuration worksheet helps you plan your configuration. Recording host server and storage array IP addresses at a single location enables you to configure your setup faster and more efficiently.

"Guidelines for Configuring NICs on Your Host Server" on page 39 provides general network setup guidelines for both Windows and Linux environments. It is recommended that you review these guidelines before completing the worksheet.

Guidelines for Configuring NICs on Your Host Server

This section provides general guidelines for setting up your network environment and IP addresses for use with the iSCSI ports on your host server and storage array. In order for hosts to communicate with management and/or iSCSI ports of storage arrays, local NICs must be configured with IP addresses capable of communication with the addresses listed in the IPv4/IPv6 worksheet. Your specific network environment may require different or additional steps than shown here, so make sure you consult with your system administrator before performing this setup.

Microsoft Windows Host Setup

To set up a Windows host network, you must configure the IP address and netmask of each iSCSI port connected to the storage array. The specific steps depend on whether you are using a Dynamic Host Configuration Protocol (DHCP) server, static IP addressing, Domain Name System (DNS) server, or Windows Internet Name Service (WINS) server.

**NOTE:** The server IP addresses must be configured for network communication to the same IP subnet as the storage array management and iSCSI ports.
If you are using a DHCP server:

1. In the Control Panel, select Network connections or Network and Sharing Center and then click Manage network connections.
2. Right-click the network connection you want to configure and select Properties.
3. On the General tab (for a local area connection) or the Networking tab (for all other connections), select Internet Protocol (TCP/IP), and then click Properties.
4. Select Obtain an IP address automatically, then click OK.

If you are using static IP addressing:

1. In the Control Panel, select Network connections or Network and Sharing Center and then click Manage network connections.
2. Right-click the network connection you want to configure and select Properties.
3. On the General tab (for a local area connection) or the Networking tab (for all other connections), select Internet Protocol (TCP/IP), and then click Properties.
4. Select Use the following IP address and enter the IP address, subnet mask, and default gateway addresses.

If you are using a DNS server:

1. In the Control Panel, select Network connections or Network and Sharing Center and then click Manage network connections.
2. Right-click the network connection you want to configure and select Properties.
3. On the General tab (for a local area connection) or the Networking tab (for all other connections), select Internet Protocol (TCP/IP), and then click Properties.
4. Select Obtain DNS server address automatically or enter the preferred and alternate DNS server IP addresses and click OK.

If you are using a WINS server:

**NOTE:** If you are using a DHCP server to allocate WINS server IP addresses, you do not need to add WINS server addresses.

1. In the Control Panel, select Network connections.
2 Right-click the network connection you want to configure and select Properties.

3 On the General tab (for a local area connection) or the Networking tab (for all other connections), select Internet Protocol (TCP/IP), and then click Properties.

4 Select Advanced → WINS tab and click Add.

5 In the TCP/IP WINS server window, type the IP address of the WINS server and click Add.

6 To enable use of the Lmhosts file to resolve remote NetBIOS names, select Enable LMHOSTS lookup.

7 To specify the location of the file that you want to import into the Lmhosts file, select Import LMHOSTS and then select the file in the Open dialog box.

8 Enable or disable NetBIOS over TCP/IP.

If using Microsoft Windows Server 2008 Core Version, use the netsh interface command to configure the iSCSI ports on the host server.

**Linux Host Setup**

To set up a Linux host network, you must configure the IP address and netmask of each iSCSI port connected to the storage array. The specific steps depend on whether you are configuring TCP/IP using DHCP or configuring TCP/IP using a static IP address.

**NOTE:** The server IP addresses must be configured for network communication to the same IP subnet as the storage array management and iSCSI ports.

If you are using DHCP (root users only):

1 Edit the /etc/sysconfig/network file:

```
NETWORKING=yes HOSTNAME=mymachine.mycompany.com
```
2. Edit the configuration file for the connection you want to configure, either
/etc/sysconfig/network-scripts/ifcfg-ethX (for Red Hat Enterprise Linux)
or /etc/sysconfig/network/ifcfg-eth-id-XX:XX:XX:XX:XX (for SUSE
Enterprise Linux).

\[
\text{BOOTPROTO}=\text{dhcp}
\]

Also, verify that an IP address and netmask are not defined.

3. Restart network services using the following command:

```
/etc/init.d/network restart
```

If you are using a static IP address (root users only):

1. Edit the /etc/sysconfig/network file as follows:

```
NETWORKING=yes HOSTNAME=mymachine.mycompany.com
GATEWAY=255.255.255.0
```

2. Edit the configuration file for the connection you want to configure, either
/etc/sysconfig/network-scripts/ifcfg-ethX (for Red Hat Enterprise Linux)
or /etc/sysconfig/network/ifcfg-eth-id-XX:XX:XX:XX:XX (for SUSE
Enterprise Linux).

```
\text{BOOTPROTO=static} \text{BROADCAST=192.168.1.255} \text{IPADDR=192.168.1.100}
\text{NETMASK=255.255.255.0} \text{NETWORK=}192.168.1.0 \text{ONBOOT=yes TYPE=Ethernet}
\text{HWADDR=XX:XX:XX:XX:XX} \text{GATEWAY=192.168.1.1}
```

3. Restart network services using the following command:

```
/etc/init.d/network restart
```

### Configuring iSCSI on Your Storage Array

The following sections contain step-by-step instructions for configuring
iSCSI on your storage array, using the Modular Disk Configuration Utility
(MDCU).

It is recommended that you use the Modular Disk Configuration Utility
(MDCU) for iSCSI configuration. The MDCU wizard guides you through
the configuration steps described above. If you want to perform a manual
configuration, see "Appendix—Manual Configuration" on page 53.
Automatic Configuration Using the Modular Disk Configuration Utility

NOTE: If MDCU is not installed, it can be installed from the MD3600i Series resource media.

The MDCU provides a consolidated approach for configuring the iSCSI network of host servers and iSCSI-based storage arrays using a wizard-driven interface. This utility also enables the user to configure the iSCSI sessions of the host server according to the best practices and to achieve load-balanced paths with the storage array iSCSI host ports.

NOTE: MDCU is only applicable to iSCSI-based MD3600i Series storage arrays.

If you select Launch the MDCU after reboot during the installation of the host software, the utility automatically launches after the next host server reboot. This utility can also be launched manually.

The utility has a context sensitive online help to guide you through each step of the wizard.

The MDCU performs:

- Storage array configuration
- Host configuration

Storage Array Configuration

Before a host iSCSI initiator and an iSCSI-based storage array can communicate, they must be configured with information such as which IP addresses and authentication method to use. Since iSCSI initiators establish connections with an already configured storage array, the first task is to configure your storage arrays to make them available for iSCSI initiators.

This utility requires network access to the management ports of the storage arrays you wish to configure. You must have a properly functioning network infrastructure before attempting to configure your storage arrays. If your storage arrays are already configured, you can skip directly to the host configuration.

This configuration task generally involves the following steps:

1. Discover available storage array(s) for configuration.
2. Select a storage array to configure.
3. Set a storage array name and password.
4. Configure the IP protocols and addresses for the management ports.
5 Configure the IP protocols and addresses for the iSCSI ports.
6 Specify the CHAP authentication method.
7 Apply the settings after reviewing a summary.
8 Repeat the process starting from step 2 to configure additional arrays.

Host Configuration (Host Connectivity Configuration)

After you have completed configuring your iSCSI-based storage arrays, the next task is to run this utility on all hosts that need to access the storage arrays. Depending on your network configuration, your host may be the same machine you use to manage your storage arrays, or it may be on a completely separate network.

The option to configure a host is disabled if the machine the utility is running on does not have an iSCSI initiator or the required driver components installed. When the option is disabled, the utility also displays an informational message. If you are running the utility on a host which is not connected to the iSCSI–based storage array (or which you do not wish to connect to the array), the informational message can be ignored.

The task generally involves the following steps:
1 Discover available storage array(s) for connection.
2 Select a storage array to connect to.
3 Specify the CHAP secret.
4 Select the iSCSI ports the host’s initiator uses to log on.
5 Repeat the process starting from step 2 to connect to additional arrays.
6 Repeat these steps on each host that needs access to the storage array(s).

Before Starting the Configuration Process

Keep the following guidelines in mind for the storage array and host configuration:

• For optimal performance, ensure your network configuration is valid by consulting the storage array’s support matrix.
• If your host has multiple network interfaces, it is recommended that each network interface uses a separate subnet.
• For redundancy in a dual controller (duplex) configuration, ensure each host network interface is configured to connect to both storage array controllers.

• For optimal load balancing, ensure each host network interface that is used for iSCSI traffic is configured to connect to each storage array controller.

• It is recommended that each host network interface only establishes one iSCSI session per storage array controller.

**NOTE:** The utility tries to follow the guidelines for the host connectivity whenever possible based on the available host network interfaces and their connectivity with the iSCSI host ports of the storage array.

**Configure the Storage Array Using MDCU**

To configure the iSCSI-based storage array(s) using the MDCU:

1. Launch the utility (if it is not launched automatically) from the server with access to the management ports of the storage array(s) to be configured.

   For Windows, click **Start** → **All Programs** → **Dell** → **MD Storage Software** → **Modular Disk Configuration Utility**.

   For Linux, click the MDCU icon on the desktop or navigate to the `/opt/dell/mdstoragesoftware/mdconfigurationutility` directory in a terminal window and run MDCU.

2. Click **Next** to continue.

3. Select the configuration task **Configure Modular Disk Storage Array** and click **Next** to continue.

4. Select the method by which the utility should discover the storage arrays for configuration and click **Next**.

   • Automatic Discovery—Automatic discovery queries the local sub-network for all iSCSI-based storage arrays and may take several minutes to complete.
• Manual Discovery—Manual discovery allows you to locate iSCSI-based storage arrays that are outside of the local sub-network. Manual discovery requires selecting whether your storage array has a single controller (simplex) or dual controllers (duplex) and whether to use IPv4 or IPv6 protocol for communicating with the management port of the storage array.

5 The next screen presents a list of the iSCSI-based storage arrays that were discovered based on the discovery process selected in step 3.

If you select Automatic Discovery, the screen displays a list of all the iSCSI-based storage arrays that were discovered in the subnet.

If you select Manual Discovery, then the list contains only the arrays whose IP addresses were entered. You can add additional arrays to the list by clicking the Add button on this screen.

You can also remove the arrays from this list by using the Remove button.

You can click Blink Array to start the blinking of the array’s front panel LED in order to locate the array physically and ensure it is the array you intend to configure. Click Stop Blinking to stop the blinking of the array before you proceed.

Select the array by clicking the radio button of the corresponding storage array and then click Next.

6 Enter the name of the storage array and the password. A password is not required during the initial configuration of the array.

If you want to set a new password for the array, select Set Password and then enter the new password in the New Password and Confirm New Password fields. Click Next to continue.

7 Select the IP protocol (IPv4/IPv6) to be used by the management ports. Also, for each protocol, select whether the configuration of the management ports’ IP addresses is to be done manually or automatically. For more information, see the online help.

Click Next to continue after selecting the protocols and the configuration method.

If you have not selected Specify Configuration Manually for any of the two protocols, then you can skip step 8.
8 If you have selected Specify Configuration Manually for any of the two protocols in the last step, a series of screens showing the backend view image of the storage array controllers is displayed. Each image contains IP addresses of the management ports of the controllers. Also, each image has one management port highlighted in red.

To use an IPv4 address for the highlighted port, enter the IP address, subnet mask and gateway address in the fields shown below the image in order to modify it.

To use an IPv6 address for the highlighted port, enter the local IP address, routable IP, and router IP address in the fields shown below the image in order to modify it.

Click Next to continue through these images to complete the configuration of all the management ports for the selected protocols.

9 Select the IP protocol (IPv4/IPv6) to be used by the iSCSI ports. Also, for each protocol, select whether the configuration of the iSCSI port IP addresses is to be done manually or automatically. For more information, see the online help.

In the drop-down menu below the protocol section, select the appropriate iSCSI port speed, either 1G or 10G. The selection must be based on the supported port speeds of the devices connected to the iSCSI ports of the storage array.

After selecting the protocols, the configuration method, and the port speed, click Next to continue.

If you have not selected Specify Configuration Manually for either of the two protocols, you can skip step 10.

10 If you selected Specify Configuration Manually for either of the two protocols in the last step, a series of screens showing the back view image of the storage array controllers is displayed. Each image contains IP addresses for the iSCSI ports of the controllers. Also, each image has one iSCSI port highlighted in red.

To use an IPv4 address for the highlighted port, enter the IP address, subnet mask and gateway address in the fields shown below the image in order to modify it.
To use an IPv6 address for the highlighted port, enter the local IP address, routable IP, and router IP address in the fields shown below the image in order to modify it.

Click Next to continue through these images to complete the configuration of all iSCSI ports for the selected protocols.

11 In the CHAP Configuration screen, select the CHAP method and click Next. For more information on CHAP see "Understanding CHAP Authentication" on page 66.

12 In the Summary screen, review the information that you entered for the storage array.

Click Apply to save the changes to the storage array.

**NOTE:** To abort the configuration for the storage array and to go back to select a storage array for configuration, click Cancel Array.

13 On the Configure Additional Arrays screen, select whether you want to configure additional array. Click Next to continue.

14 If you selected Yes in the above step, then start again from step 4.

15 If you selected No in step 14, then on the Configure Host Connectivity screen, select whether you want to configure the connectivity for current host’s iSCSI initiator. Click Next to continue.

If you selected No above, then you are done with the configuration task.

Click Finish on the final screen to exit the utility.

16 If you selected Yes in the last step, then the Select Storage Array screen is displayed. Select the storage array that you want to configure for connectivity to the local host.

**NOTE:** The storage arrays configured by the utility are marked as Configuration Complete against their names in the list. This helps you to identify the arrays that are ready to be configured for host access.

17 In the Storage Array Login screen, in the Controller# column, select the iSCSI host port of the storage array that needs to be configured and it’s IP address(es). In the Host Address column, from drop-down menu list, select the host IP address that will log in to the iSCSI host port of the storage array.
See "Source Port Selection for iSCSI Host Ports" on page 51 for more information about how these host IP addresses are listed in the drop-down menu and the recommended guidelines for selecting the host IP addresses.

18 Click Next to continue to enter the login information for another controller or Click Apply to save the login information.

19 In the Connect to Additional Arrays screen, select whether you want to connect to another storage array or not.

**NOTE:** If you want to connect to another storage array, repeat the above steps starting from step 16. If you do not want to connect to additional arrays, then click Finish on the final screen to exit the utility.

**Configure the Host Connectivity Using MDCU**

To configure the host connectivity for an iSCSI-based storage array(s) using MDCU:

1 Launch the utility (if it is not launched automatically) from the server which needs to be configured for access to the iSCSI-based storage array(s). This server must have access to the array either using the array’s management ports or using the array’s iSCSI host ports.

   See step 1 in "Configure the Storage Array Using MDCU" on page 45 for the instructions on how to launch the utility.

   Click Next to continue.

2 In the Configuration Task screen, select Configure Host and click Next.

   **NOTE:** This task is not supported or is disabled if the MDSM agent is not installed on the host where you are running the utility. The agent is typically not installed on the Windows client systems such as Windows XP.
In the **Discovery Method** screen, select one of the following discovery methods:

- If the host has access to the management ports of the MD storage array(s), then select **Discover via Management Port** method and click **Next**.
- If the host does not have the access to the management ports of the array, then select the **Discover via iSCSI Port** method (assuming that the host has access to the iSCSI host ports of the storage array) and click **Next**. Continue to step 5.

Follow the instructions in step 3 and step 4 of "Configure the Storage Array Using MDCU" on page 45 to select the storage array that needs to be configured for connectivity with the host. Go to step 6.

In the **iSCSI Port IP Address** screen, enter the IPv4 IP address of any one of the iSCSI host port of the array that the host can connect to or enter the IPv6 local address of any of the iSCSI host port. Click **Next** to continue.

In the **CHAP Configuration** screen, enter the CHAP secret if you have configured a CHAP secret for the storage array.

In the **Storage Array Login** screen, in the Controller# column, select the iSCSI host port of the storage array that needs to be configured and its IP address(es). In the **Host Address** column, from drop-down menu list, select the host IP address that logs into the iSCSI host port of the storage array. See "Source Port Selection for iSCSI Host Ports" on page 51 for more details about how these host IP addresses are listed in the drop-down menu and the recommended guidelines for selecting the host IP addresses.

Click **Next** to continue to enter the login information for another controller or Click **Apply** to commit the array login information.

In the **Connect to Additional Arrays** screen, select whether you want to connect to another storage array or not.

If you want to connect to another storage array, repeat the above steps starting from step 4 or step 5 depending on your last selection.

If you do not want to connect to additional arrays, then click **Finish** on the final screen to exit the utility.
Source Port Selection for iSCSI Host Ports

In order to establish data communication between a host and an iSCSI-based storage array, the iSCSI initiator on the host must be configured to establish iSCSI sessions to the iSCSI host ports of the storage array. The iSCSI port login screen allows you to specify the host and storage array IP addresses the iSCSI initiator uses to establish these iSCSI sessions.

Port Login Selection

Each iSCSI port for each controller in the storage array is presented with a list of host IP addresses through which the iSCSI initiator is able to log in. The host IP addresses are the source IP addresses and the iSCSI port is the target. Each list contains only the host IP addresses that are able to communicate with the associated iSCSI port. If none of the host IP addresses are able to communicate with an iSCSI port, Not Available is the only option shown for that iSCSI port. If none of the host IP addresses are able to communicate with any iSCSI ports of either storage array controller, the host configuration option is aborted for that storage array.

NOTE: The behavior described in the preceding paragraph does not apply to Microsoft Windows Server 2003.

For Microsoft Windows Server 2003, each list contains all available host IP addresses regardless of whether or not the address is able to communicate with the associated iSCSI port. You must select the appropriate host IP addresses for each iSCSI port.

Automatic Selection

The utility attempts to automatically find and select the best possible configuration of host IP address(es) and storage array iSCSI ports for optimal performance and redundancy.

This automatic selection attempts to ensure that a host IP address (up to two IP addresses for MD3000i and MD3600i storage arrays and up to four IP addresses for MD3200i) establishes an iSCSI session with each storage array controller and that the host IP address is logged in to a maximum of one iSCSI port per controller. Configuration in this manner ensures redundancy and load balancing among the multiple host IP addresses (NICs).
The **Do Not Connect** option may be selected as the default option if the utility recommends not to connect to the iSCSI port. Also, even if the best recommended configuration is presented (whenever possible), you can still override this configuration by selecting the other host IP addresses from the drop-down list.

**Suboptimal Configuration Warnings**

In the following cases, a warning is displayed, that you must confirm, to continue:

- The host IP addresses are selected in such a way that any host IP address establishes an iSCSI session with only one storage array controller in a dual controller (duplex) configuration.
- The host IP addresses are selected in such a way that a host IP address establishes two or more iSCSI sessions with the same storage array controller.

**Post Connection Establishment Steps**

After iSCSI connectivity is established between the host server(s) and the storage array, a few additional steps are required before reading and writing to the array. To summarize these steps, you will need to:

- Create disk groups and virtual disks
- Perform host-to-virtual disk mapping
- Complete operating system specific device recognition, partitioning, and file system creation

To get detailed information regarding the first two tasks, refer to the **Owner’s Manual**, specifically, the sections entitled **Creating Disk Groups and Virtual Disks** and **Host-to-Virtual Disk Mapping**. The **Owner’s Manual** can be found at [support.dell.com/manuals](http://support.dell.com/manuals).

For the final task, the source for your documentation will depend on your operating system.
• Windows—Refer to Windows’ Disk Manager help files. To access Disk Manager, go to Start→Control Panel→Administrative Tools→Computer Management.

• Linux—Two options are available:
  – To perform these tasks using the command line, refer to the Configuration: Device Mapper Multipath for Linux chapter in the Owner’s Manual.
  – To utilize a graphical interface solution, Dell has created the Device Mapper Utility (DMU), which provides the ability to discover and manage the configuration of Linux Device Mapper devices for Dell Modular Disk series storage arrays. This utility helps you set up and manage partitions on the virtual disks of storage arrays mapped to a Linux server. Go to http://support.dell.com/support/downloads/, and search for DMU. Download and run the utility. For more details on the use of DMU, refer to the online help files within the utility.
Uninstalling Software

Uninstalling From Microsoft Windows

Use the Change/Remove Program feature to uninstall Modular Disk Storage Software (MDSS) from Microsoft Windows operating systems other than Microsoft Windows Server 2008:

1. From the Control Panel, double-click Add or Remove Programs.
2. Select Dell MD36xxi Storage Software from the list of programs.
3. Click Change/Remove, and follow the instructions to complete the uninstallation process.
   The Uninstall Complete window appears.
4. Select Yes to restart the system, and then click Done.

Use the following procedure to uninstall Modular Disk Storage software from Windows Server 2008 GUI versions:

1. From the Control Panel, double-click Programs and Features.
2. Select MD Storage Manager from the list of programs.
3. Click Uninstall/Change, then follow the instructions to complete the uninstallation process.
   The Uninstall Complete window appears.
4. Select Yes to restart the system, then click Done.

Use the following procedure to uninstall Modular Disk Storage Software on Windows Server 2008 Core versions:

1. Navigate to the \Program Files\Dell\MD Storage Software\Uninstall Dell 36xxi Storage Software directory.

**NOTE:** By default, MD Storage Manager is installed in the \Program Files\Dell\MD Storage Software directory. If another directory was used during installation, navigate to that directory before beginning the uninstallation procedure.
2 From the installation directory, type the following command and press <Enter>:

   Uninstall Dell MD36xxi Storage Software

3 From the Uninstall window, click Next and follow the instructions on the screen.

4 Select Yes to restart the system, then click Done.

**Uninstalling From Linux**

1 By default, MD Storage Manager is installed in the /opt/dell/mdstoragemanager/Uninstall Dell MD36xxi Storage Software directory. If another directory was used during installation, navigate to that directory before beginning the uninstallation procedure.

2 From the installation directory, type the following command and press <Enter>:

   ./Uninstall\ Dell\ MD36xxi\ Storage\ Software

3 From the Uninstall window, click Next, and follow the instructions on the screen.

   While the software is uninstalling, the Uninstall window is displayed. When the uninstall procedure is complete, the Uninstall Complete window is displayed.

4 Click Done.
Appendix—Manual Configuration of iSCSI

The following sections contain step-by-step instructions for configuring iSCSI on your storage array. However, before beginning, it is important to understand where each of these steps occur in relation to your host server or the storage array environment.

Table A-1 shows each iSCSI configuration step and where it occurs.

<table>
<thead>
<tr>
<th>This Step is Performed on the Host Server</th>
<th>This Step is Performed on the Storage Array Using MD Storage Manager</th>

</tbody>
</table>
Appendix—Manual Configuration of iSCSI

Step 1: Discover the Storage Array (Out-of-band Management Only)

Default Management IPv4 Port Settings

By default, the storage array management ports are set to Dynamic Host Configuration Protocol (DHCP). If the controller(s) on your storage array is/are unable to get IP configuration from a DHCP server, it times out after 10 seconds and falls back to a default static IP address. The default IP configuration is:

Controller 0: IP: 192.168.128.101 Subnet Mask: 255.255.255.0
Controller 1: IP: 192.168.128.102 Subnet Mask: 255.255.255.0

NOTE: No default gateway is set.

NOTE: If DHCP is not used, perform the initial configuration using the management station on the same physical subnet as the storage array. Additionally, during initial configuration, configure at least one network adapter on the same IP subnet as the storage array’s default management port (192.168.128.101 or 192.168.128.102). After initial configuration (management ports are configured using MD Storage Manager), you can change the management station’s IP address back to its previous settings.

Default Management IPv6 Port Settings

By default, the storage array management ports are enabled for IPv6 stateless auto-configuration. The ports are automatically configured to respond to their link local address and to a routable address if a configured IPv6 router is present on the network. To know the link local addresses of the management port, see the MAC label for the management port on the controller. For example:

1. If the MAC Address is 00:08:74:AA:BB:CC, the link local address starts with FE80::02.
2. Add the second and third bytes 08:74 MAC address to the prefix FE80::0208:744.
3. Add FF:FE to obtain FE80::0200:08FF:FE.
Finally, add the last three bytes of the MAC address FE80::0200:08FF:FEAA:BBCC.

NOTE: This procedure applies to out-of-band management only. If you choose to set up in-band management, you must complete this step and then proceed to "Step 8: (Optional) Set Up In-Band Management" on page 76.

You can discover the storage array either automatically or manually. Select one and complete the following procedure.

**Automatic Storage Array Discovery**

1. Launch MD Storage Manager (MDSM).
   
   If this is the first storage array to be set up, the Add New Storage Array window appears.

2. Select Automatic and click OK.
   
   It may take several minutes for the discovery process to complete. Closing the discovery status window before the discovery process completes cancels the discovery process.
After discovery is complete, a confirmation screen appears.

3 Click Close to close the screen.

**Manual Storage Array Discovery**

1 Launch MDSM.

If this is the first storage array to be set up, the Add New Storage Array window appears.

2 Select Manual and click OK.

3 Select Out-of-band management and enter the host server name(s) or IP address(es) of the iSCSI storage array controller.

4 Click Add.

Out-of-band management should now be successfully configured.

After discovery is complete, a confirmation screen appears.

5 Click Close to close the screen.

**Setting Up the Array**

1 When discovery is complete, the name of the first storage array found appears under the Summary tab in MDSM.

2 The default name for the newly discovered storage array is Unnamed. If another name appears, click the down arrow next to that name and select Unnamed in the drop-down list.

3 Click the Initial Setup Tasks option to see links to the remaining post-installation tasks. For more information about each task, see the Owner’s Manual. Perform these tasks in the order shown in Table A-2.

**NOTE:** Before configuring the storage array, check the status icons on the Summary tab to ensure that the enclosures in the storage array are in an Optimal status. For more information on the status icons, see the Owner’s Manual at support.dell.com/manuals.
Step 2: Configure the iSCSI Ports on the Storage Array

By default, the iSCSI ports on the storage array are set to the following IPv4 settings:

Controller 0, Port 0: IP: 192.168.130.101 Subnet Mask: 255.255.255.0 Port: 3260
Controller 0, Port 1: IP: 192.168.131.101 Subnet Mask: 255.255.255.0 Port: 3260
Controller 0, Port 2: IP: 192.168.132.101 Subnet Mask: 255.255.255.0 Port: 3260
Controller 0, Port 3: IP: 192.168.133.101 Subnet Mask: 255.255.255.0 Port: 3260
Controller 1, Port 0: IP: 192.168.130.102 Subnet Mask: 255.255.255.0 Port: 3260
Controller 1, Port 1: IP: 192.168.131.102 Subnet Mask: 255.255.255.0 Port: 3260

Table A-2. Initial Setup Tasks Dialog Box

<table>
<thead>
<tr>
<th>Task</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rename the storage array</td>
<td>To provide a more meaningful name than the software-assigned label, Unnamed.</td>
</tr>
<tr>
<td>Set a storage array password</td>
<td>To restrict unauthorized access. MDSM may ask for a password before changing the configuration or performing a destructive operation.</td>
</tr>
<tr>
<td>Set up alert notifications</td>
<td>To notify individuals (by e-mail) and/or storage enterprise management consoles, such as Dell Management Console, (by SNMP) when a storage array component degrades or fails, or an adverse environmental condition occurs.</td>
</tr>
<tr>
<td>Set up e-mail alerts</td>
<td></td>
</tr>
<tr>
<td>Set up SNMP alerts</td>
<td></td>
</tr>
<tr>
<td>Configure a storage array</td>
<td>To create virtual disks and map them to hosts.</td>
</tr>
</tbody>
</table>
Controller 1, Port 2: IP: 192.168.132.102 Subnet Mask: 255.255.255.0 Port: 3260

Controller 1, Port 3: IP: 192.168.133.102 Subnet Mask: 255.255.255.0 Port: 3260

NOTE: No default gateway is set.

To configure the iSCSI ports on the storage array:

1. From MDSM navigate to the Setup tab on the AMW.
2. Click configure Ethernet management ports and then select Configure iSCSI Host Ports.
3. Configure the iSCSI ports on the storage array.

NOTE: Using static IPv4 addressing is recommended, although DHCP is supported.

The following settings are available (depending on the configuration) by clicking the Advanced button:

- Virtual LAN (VLAN) support—A VLAN is a network of different systems that behave as if they are connected to the same segments of a local area network (LAN) and are supported by the same switches and routers. When configured as a VLAN, a device can be moved to another location without being reconfigured. To use VLAN on your storage array, obtain the VLAN ID from your network administrator.
- Ethernet priority—This parameter is set to determine a network access priority.
- TCP listening port—The port number on the storage array that listens for iSCSI logins from host server iSCSI initiators.

NOTE: The TCP listening port for the iSNS server is the port number the storage array controller uses to connect to an iSNS server. This allows the iSNS server to register the iSCSI target and portals of the storage array so that the host server initiators can identify them.
- Jumbo frames—Jumbo Ethernet frames are created when the maximum transmission units (MTUs) are larger than 1500 bytes per frame. This setting is adjustable port-by-port.

4. To enable ICMP PING responses for all ports, select Enable ICMP PING responses.
5. Click OK when all iSCSI storage array port configurations are complete.
6 Test the connection by performing a ping command on each iSCSI storage array port.

**Step 3: Perform Target Discovery From the iSCSI Initiator**

This step identifies the iSCSI ports on the storage array to the host server. Select the set of steps in one of the following sections (Microsoft Windows or Linux) that corresponds to your operating system.

If you are using **Microsoft Windows Server 2003** or **Windows Server 2008 GUI version**:

1 Click Start → Programs → Microsoft iSCSI Initiator or click Start → All Programs → Administrative Tools → iSCSI Initiator.

2 Click the Discovery tab.

3 Under Target Portals, click Add and enter the IP address or DNS name of the iSCSI port on the storage array.

4 If the iSCSI storage array uses a custom TCP port, change the Port number. The default is 3260.

5 Click Advanced and set the following values on the General tab:
   - **Local Adapter**—Must be set to Microsoft iSCSI Initiator.
   - **Source IP**—The source IP address of the host you want to connect with.
   - **Data Digest and Header Digest**—Optionally, you can specify that a digest of data or header information be compiled during transmission to assist in troubleshooting.
   - **CHAP logon information**—Leave this option unselected and do not enter CHAP information at this point, unless you are adding the storage array to a Storage Area Network (SAN) that has target CHAP already configured.

**NOTE:** IPSec is not supported.

6 Click OK to exit the Advanced menu and click OK again to exit the Add Target Portals screen.

7 To exit the Discovery tab, click OK.
If you plan to configure CHAP authentication, do not perform discovery on more than one iSCSI port at this point. Go to "Step 4: Configure Host Access" on page 65.

If you do not plan to configure CHAP authentication, repeat step 1 thorough step 6 for all iSCSI ports on the storage array.

If you are using Windows Server 2008 Core Version:

1. Set the iSCSI initiator service to start automatically:
   
   sc \<server_name> config msiscsi start=auto

2. Start the iSCSI service:

   sc start msiscsi

3. Add a target portal:

   iscsicli QAddTargetPortal
   <IP_address_of_iSCSI_port_on_storage_array>

If you are using Red Hat Enterprise Linux 5, Red Hat Enterprise Linux 6, SUSE Linux Enterprise Server 10, or SUSE Linux Enterprise Server 11:

Configuration of the iSCSI initiator for Red Hat Enterprise Linux 5 and SUSE Linux Enterprise Server 10 SP1 distributions is done by modifying the /etc/iscsi/iscsid.conf file, which is installed by default when you install MDSM. You can edit the file directly, or replace the default file with a sample file included on the PowerVault MD3600i Series resource media.

To use the sample file included on the media:

1. Make a copy of the default /etc/iscsi/iscsid.conf file by saving it to another directory of your choice.

2. Edit the following entries in the /etc/iscsi/iscsid.conf file:

   a. Edit or verify that the node.startup = manual line is disabled.

   b. Edit or verify that the node.startup = automatic line is enabled. This enables automatic startup of the service at boot time.

   c. Verify that the following time-out value is set to 30:

      node.session.timeo.replacement_timeout = 30

   d. Save and close the /etc/iscsi/iscsid.conf file.

3. From the console, restart the iSCSI service with the following command:

   service iscsi start
4  Verify that the iSCSI service is running during boot using the following command from the console:
   
   ```bash
   chkconfig iscsi on
   ```

5  To display the available iSCSI targets at the specified IP address, use the following command:
   
   ```bash
   iscsiadm -m discovery -t st -p
   <IP_address_of_iSCSI_port>
   ```

6  After target discovery, use the following command to manually log in:
   
   ```bash
   iscsiadm -m node -l
   ```
   This login is performed automatically at startup if automatic startup is enabled.

7  Manually log out of the session using the following command:
   
   ```bash
   iscsiadm -m node -T <initiator_username> -p
   <target_ip> -u
   ```

**Step 4: Configure Host Access**

This step specifies which host servers access virtual disks on the storage array. You should perform this step before mapping virtual disks to host servers or any time you connect new host servers to the storage array.

1  Launch MDSM.

2  Navigate to the AMW and click **Manually define hosts**.

3  At **Enter host name**, enter the host server for virtual disk mapping.
   
   This can be an informal name, not necessarily a name used to identify the host server to the network.

4  Select a method for adding the host port identifier.

5  Select the host type.

6  Select whether or not the host server will be part of a host server group that shares access to the same virtual disks as other host servers. Select **Yes** only if the host is part of a Microsoft cluster.

7  Click **Next**.

8  Specify if this host will be part of a host group, and click **Finish**.
Understanding CHAP Authentication

What is CHAP?
Challenge Handshake Authentication Protocol (CHAP) is an optional iSCSI authentication method where the storage array (target) authenticates iSCSI initiators on the host server. Two types of CHAP are supported:

- Target CHAP
- Mutual CHAP

Target CHAP
In target CHAP, the storage array authenticates all requests for access issued by the iSCSI initiator(s) on the host server using a CHAP secret. To set up target CHAP authentication, you must enter a CHAP secret on the storage array, then configure each iSCSI initiator on the host server to send that secret each time it attempts to access the storage array.

Mutual CHAP
In addition to setting up target CHAP, you can set up mutual CHAP in which both the storage array and the iSCSI initiator authenticate each other. To set up mutual CHAP, configure the iSCSI initiator with a CHAP secret that the storage array must send to the host server in order to establish a connection. In this two-way authentication process, both the host server and the storage array send information that the other must validate before a connection is allowed.

CHAP is an optional feature and is not required to use iSCSI. However, if you do not configure CHAP authentication, any host server connected to the same IP network as the storage array can read from and write to the storage array.

**NOTE:** When using CHAP authentication, you should configure it on both the storage array (using MDSM) and the host server (using the iSCSI initiator) before preparing virtual disks to receive data. If you prepare disks to receive data before you configure CHAP authentication, you lose visibility to the disks once CHAP is configured.

CHAP Definitions
To summarize the differences between target CHAP and mutual CHAP authentication, see Table A-3.
Step 5: Configure CHAP Authentication on the Storage Array (Optional)

If you are configuring CHAP authentication of any kind (either target-only or target and mutual), you must complete this step and "Step 5: Configure CHAP Authentication on the Storage Array (Optional)" on page 67.

If you are not configuring any type of CHAP, skip these steps and go to "Step 7: Connect to the Target Storage Array From the Host Server" on page 73.

**NOTE:** If you choose to configure mutual CHAP authentication, configure target CHAP first.

In terms of iSCSI configuration, the term target always refers to the storage array.

**Configuring Target CHAP Authentication on the Storage Array**

1. From MDSM, click the iSCSI tab and then click Change Target Authentication.
   
   Select one of the CHAP settings described in Table A-4.

2. To configure a CHAP secret, select CHAP and select CHAP Secret.

3. Enter the Target CHAP Secret (or Generate Random Secret). Confirm it in Confirm Target CHAP Secret and click OK.

---

### Table A-3. CHAP Types Defined

<table>
<thead>
<tr>
<th>CHAP Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target CHAP</td>
<td>Sets up accounts that iSCSI initiators use to connect to the target storage array. The target storage array then authenticates the iSCSI initiator.</td>
</tr>
<tr>
<td>Mutual CHAP</td>
<td>Applied in addition to target CHAP, mutual CHAP sets up an account that a target storage array uses to connect to an iSCSI initiator. The iSCSI initiator then authenticates the target.</td>
</tr>
</tbody>
</table>
Although the storage array allows sizes from 12 to 57 characters, many initiators only support CHAP secret sizes up to 16 characters (128-bit).

**NOTE:** A CHAP secret is not retrievable after it is entered. Ensure that you record the secret in an accessible place. If Generate Random Secret is used, copy and paste the secret into a text file for future reference since the same CHAP secret is used to authenticate any new host servers you may add to the storage array. If you forget this CHAP secret, you must disconnect all existing hosts attached to the storage array and repeat the steps in this chapter to re-add them.

4 Click **OK**.

<table>
<thead>
<tr>
<th>Table A-4. CHAP Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Option</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
<tr>
<td>None and CHAP</td>
</tr>
<tr>
<td>CHAP</td>
</tr>
</tbody>
</table>

**Configuring Mutual CHAP Authentication on the Storage Array**

The initiator secret must be unique for each host server that connects to the storage array and must not be the same as the target CHAP secret.

Change the initiator authentication settings in the Change Target Authentication window. Use these options to change the settings:

- **None**—Select None if you permit no initiator authentication. If you select None, any initiator can access this target. Use this option only if you do not require secure data. However, you can select both None and CHAP at the same time.

- **CHAP**—Select CHAP if you want to enable an initiator that tries to access the target to authenticate using CHAP. Define the CHAP secret only if you want to use mutual CHAP authentication. If you select CHAP, and if no CHAP target secret is defined, an error message appears. Click CHAP Secret to view the Enter CHAP Secret windows. Use this window to define the CHAP secrets.
Appendix—Manual Configuration of iSCSI

NOTE: To remove a CHAP secret, you must delete the host initiator and re-add it.

Step 6: Configure CHAP Authentication on the Host Server (Optional)

If you configured CHAP authentication in "Step 5: Configure CHAP Authentication on the Storage Array (Optional)" on page 67, complete the following steps. If not, skip to "Step 7: Connect to the Target Storage Array From the Host Server" on page 73.

Select the set of steps in one of the following sections (Windows or Linux) that corresponds to your operating system.

If you are using Windows Server 2008 GUI version:

1. Click Start→Programs→Microsoft iSCSI Initiator or click Start→All Programs→Administrative Tools→iSCSI Initiator.

2. If you are not using mutual CHAP authentication, go to step 4.

3. If you are using mutual CHAP authentication, click the General tab and select Secret. At Enter a secure secret, enter the mutual CHAP secret you entered for the storage array

4. Click the Discovery tab.

5. Under Target Portals, select the IP address of the iSCSI port on the storage array and click Remove.

The iSCSI port you configured on the storage array during target discovery disappears.

6. Under Target Portals, click Add and re-enter the IP address or DNS name of the iSCSI port on the storage array (removed above).

7. Click Advanced and set the following values on the General tab:
   • Local Adapter—Should always be set to Microsoft iSCSI Initiator.
   • Source IP—The source IP address of the host you want to connect with.
   • Data Digest and Header Digest—Optionally, you can specify that a digest of data or header information be compiled during transmission to assist in troubleshooting.
• CHAP logon information—Enter the target CHAP authentication user name and secret you entered (for the host server) on the storage array.

• Perform mutual authentication—if mutual CHAP authentication is configured, select this option.

**NOTE:** IPSec is not supported.

8 Click OK.

If you require a discovery session failover, repeat step 5 and step 6 (in this procedure) for all iSCSI ports on the storage array. Otherwise, single-host port configuration is sufficient.

**NOTE:** If the connection fails, ensure that all IP addresses are entered correctly. Mistyped IP addresses result in connection problems.

If you are using Windows Server 2008 Core version:

1 Set the iSCSI initiator services to start automatically (if not already set):
   \sc \<server_name> config msiscsi start=auto

2 Start the iSCSI service (if necessary):
   \sc start msiscsi

3 If you are not using mutual CHAP authentication, go to step 5.

4 Enter the mutual CHAP secret you entered for the storage array:
   \iscsicli CHAPSecret <secret>

5 Remove the target portal that you configured on the storage array during target discovery:
   \iscsicli RemoveTargetPortal <IP_address> <TCP_listening_port>

6 Add the target portal with CHAP defined:
   \iscsicli QAddTargetPortal
   <IP_address_of_iSCSI_port_on_storage_array> [CHAP_username]
   [CHAP_password]

   where, [CHAP_username] is the initiator name and [CHAP_password] is the target CHAP secret.

   If you require a discovery session failover, repeat step 5 for all iSCSI ports on the storage array. Otherwise, single-host port configuration is sufficient.
If you are using Red Hat Enterprise Linux 5, Red Hat Enterprise Linux 6, SUSE Linux Enterprise Server 10, or SUSE Linux Enterprise Server 11:

1. To enable CHAP (optional), the following line needs to be enabled in your `/etc/iscsi/iscsid.conf` file:

   ```
   node.session.auth.authmethod = CHAP
   ```

2. To set a user name and password for CHAP authentication of the initiator by the target(s), edit the following lines:

   ```
   node.session.auth.username = <iscsi_initiator_username>
   node.session.auth.password = <CHAP_initiator_password>
   ```

3. If you are using Mutual CHAP authentication, you can set the user name and password for CHAP authentication of the target(s) by the initiator by editing the following lines:

   ```
   node.session.auth.username_in = <iscsi_target_username>
   node.session.auth.password_in = <CHAP_target_password>
   ```

4. To set up discovery session CHAP authentication, first uncomment the following line:

   ```
   discovery.sendtargets.auth.authmethod = CHAP
   ```

5. Set a user name and password for a discovery session CHAP authentication of the initiator by the target(s) by editing the following lines:

   ```
   discovery.sendtargets.auth.username = <iscsi_initiator_username>
   discovery.sendtargets.auth.password = <CHAP_initiator_password>
   ```

6. To set the user name and password for discovery session CHAP authentication of the target(s) by the initiator for Mutual CHAP, edit the following lines:

   ```
   discovery.sendtargets.auth.username = <iscsi_target_username>
   ```
discovery.sendtargets.auth.password_in = <CHAP_target_password>

7 The final configuration contained in the /etc/iscsi/iscsid.conf file might look like this:
	node.session.auth.authmethod = CHAP
	node.session.auth.username = iqn.2005-03.com.redhat01.78b1b8cad821
	node.session.auth.password = password_1
	node.session.auth.username_in= iqn.1984-05.com.dell:powervault.123456
	node.session.auth.password_in = test1234567890

discovery.sendtargets.auth.authmethod = CHAP

discovery.sendtargets.auth.username = iqn.2005-03.com.redhat01.78b1b8cad821

discovery.sendtargets.auth.password = password_1

discovery.sendtargets.auth.username = iqn.1984-05.com.dell:powervault.123456

discovery.sendtargets.auth.password_in = test1234567890

If you are using SUSE Linux Enterprise Server SP3 using the GUI:

1 Click Desktop→YaST→iSCSI Initiator.
2 Click Service Start, then select When Booting.
3 Select Discovered Targets, then select Discovery.
4 Enter the IP address of the port.
5 Click Next.
6 Select any target that is not logged in and click Log in.
7 Select one:
   • If you are not using CHAP authentication, select **No Authentication**. Go to step 8.
   or
   • If you are using CHAP authentication, enter the CHAP user name and password. To enable Mutual CHAP, select and enter the Mutual CHAP user name and password.

8 Repeat step 7 for each target until at least one connection is logged in for each controller.

9 Go to **Connected Targets**.

10 Verify that the targets are connected and displays a status of **true**.

### Step 7: Connect to the Target Storage Array From the Host Server

If you are using **Windows Server 2008 GUI**:

1 Click **Start**→**Programs**→**Microsoft iSCSI Initiator** or click **Start**→**All Programs**→**Administrative Tools**→**iSCSI Initiator**.

2 Click the **Targets** tab.
   If previous target discovery was successful, the **iqn** of the storage array should be displayed under **Targets**.

3 Click **Log On**.

4 Select **Automatically restore this connection when the system boots**.

5 Select **Enable multi-path**.

6 Click **Advanced** and configure the following settings under the **General** tab:
   • **Local Adapter**—Must be set to **Microsoft iSCSI Initiator**.
   • **Source IP**—The source IP address of the host server you want to connect from.
   • **Target Portal**—Select the iSCSI port on the storage array controller that you want to connect to.
• **Data Digest and Header Digest**—Optionally, you can specify that a digest of data or header information be compiled during transmission to assist in troubleshooting.

• **CHAP logon information**—If CHAP authentication is required, select this option and enter the Target secret.

• **Perform mutual authentication**—If mutual CHAP authentication is configured, select this option.

⚠️ **NOTE:** IPSec is not supported.

7 Click OK.

To support storage array controller failover, the host server must be connected to at least one iSCSI port on each controller. Repeat step 3 through step 8 for each iSCSI port on the storage array that you want to establish as failover targets. The **Target Portal** address is different for each port you connected to.

⚠️ **NOTE:** To enable the higher throughput of multipathing I/O, the host server must connect to both iSCSI ports on each controller, ideally from separate host-side NICs. Repeat step 3 through step 7 for each iSCSI port on each controller. If using a duplex MD36x0i configuration, then LUNs should also be balanced between the controllers.

The **Status** field on the **Targets** tab should now display as **Connected**.

8 Click OK to close the Microsoft iSCSI initiator.

⚠️ **NOTE:** PowerVault MD36x0i supports only round-robin load-balancing policies.

If you are using **Windows Server 2008 Core Version**:

1 Set the iSCSI initiator services to start automatically (if not already set):
   ```
   sc \<server_name> config msiscsi start=auto
   ```

2 Start the iSCSI service (if necessary):
   ```
   sc start msiscsi
   ```

3 Log on to the target:
   ```
   iscsicli PersistentLoginTarget <Target_Name> <Report_To_PNP> <Target_Portal_Address> \<TCP_Port_Number_Of_Target_Portal> * * *
   <Login_Flags> * * * * * <Username> <Password> <Authtype> * <Mapping_Count>
   ```
where,

- `<Target_Name>` is the target name as displayed in the target list. Use the `iscsicli ListTargets` command to display the target list.
- `<Report_To_PNP>` is 'T', which exposes the LUN to the operating system as a storage device.
- `<Target_Portal_Address>` is the IP address of the iSCSI port on the controller being logged in to.
- `<TCP_Port_Number_Of_Target_Portal>` is 3260.
- `<Login_Flags>` is 0x2 to enable multipathing for the target on the initiator. This value allows more than one session to be logged in to a target at one time.
- `<Username>` is the initiator name.
- `<Password>` is the target CHAP secret.
- `<Authtype>` is either 0 for no authentication, 1 for Target CHAP, or 2 for Mutual CHAP.

**NOTE:** `<Username>`, `<Password>` and `<Authtype>` are optional parameters. They can be replaced with an asterisk (*) if CHAP is not used.

- `<Mapping_Count>` is 0, indicating that no mappings are specified and no further parameters are required.

* * * An asterisk (*) represents the default value of a parameter.

For example, your log on command might look like this:

```
iscsicli PersistentLoginTarget iqn.1984-05.com.dell:powerware.6001372000ffe332xx000004672edf2 3260 T 192.168.130.101 * * * 0x2 * * * * * * * * * * * * 0
```

To view active sessions to the target, run the following command:

```
iscsicli SessionList
```

To support storage array controller failover, the host server must be connected to at least one iSCSI port on each controller. Repeat step 3 for each iSCSI port on the storage array that you want to establish as a failover target. The `Target_Portal_Address` is different for each port you connect to.
PersistentLoginTarget does not initiate a login to the target until after the system is rebooted. To establish immediate login to the target, substitute LoginTarget for PersistentLoginTarget.

**NOTE:** See the Microsoft iSCSI Software Initiator 2.x User’s Guide for more information about the commands used in the previous steps. For more information about Windows Server 2008 Server Core, see the Microsoft Developers Network (MSDN) at microsoft.com.

If you are using a Linux Server:

In MDSM, the Configure iSCSI Host Ports displays the status of each iSCSI port you attempt to connect and the configuration state of all IP addresses. If either displays Disconnected or Unconfigured, respectively, check the following and repeat the iSCSI configuration steps:

- Are all cables securely attached to each port on the host server and storage array?
- Is TCP/IP correctly configured on all target host ports?
- Is CHAP set up correctly on both the host server and the storage array?

To review optimal network setup and configuration settings, see "Guidelines for Configuring NICs on Your Host Server" on page 39.

**Step 8: (Optional) Set Up In-Band Management**

Out-of-band management (see "Step 1: Discover the Storage Array (Out-of-band Management Only)" on page 58) is the recommended method for managing the storage array. However, to optionally set up in-band management, follow the procedure given below.

The default iSCSI host port IPv4 addresses are shown below for reference:

- Controller 0, Port 0: IP: 192.168.130.101
- Controller 0, Port 1: IP: 192.168.131.101
- Controller 0, Port 0: IP: 192.168.132.101
- Controller 0, Port 1: IP: 192.168.133.101
- Controller 1, Port 0: IP: 192.168.130.102
- Controller 1, Port 1: IP: 192.168.131.102
- Controller 1, Port 0: IP: 192.168.132.102
- Controller 1, Port 1: IP: 192.168.133.102
**NOTE:** Configure the management station you are using for network communication to the same IP subnet as the MD36x0i host ports.

1. Establish an iSCSI session to the MD3600i RAID storage array.
2. Restart the SMagent service.
3. Launch MDSM.
   If this is the first storage array to be set up for management, the Add New Storage Array window appears. Otherwise, click New.
4. Select Manual and click OK.
5. Select In-band management and enter the host server name(s) or IP address(es) of the host server that is running the MD Storage Manager software.
6. Click Add.
   In-band management should now be successfully configured.
Appendix—Load Balancing

Load Balance Policy

Multi-path drivers select the I/O path to a virtual disk through a specific RAID controller module. When the multi-path driver receives a new I/O to process, the driver tries to find a path to the current RAID controller module that owns the virtual disk. If the path to the current RAID controller module that owns the virtual disk cannot be found, the multi-path driver migrates the virtual disk ownership to the secondary RAID controller module. When multiple paths to the RAID controller module that owns the virtual disk exist, you can choose a load balance policy to determine which path is used to process I/O. Multiple options for setting the load balance policies let you optimize I/O performance when mixed host interfaces are configured.

You can choose one of the following load balance policies to optimize I/O performance:

- Round robin with subset
- Least queue depth with subset
- Least path weight with subset (Microsoft Windows operating systems only)

Round Robin With Subset

The round robin with subset I/O load balance policy routes I/O requests, in rotation, to each available data path to the RAID controller module that owns the virtual disks. This policy treats all paths to the RAID controller module that owns the virtual disk equally for I/O activity. Paths to the secondary RAID controller module are ignored until ownership changes. The basic assumption for the round-robin policy is that the data paths are equal. With mixed host support, the data paths might have different bandwidths or different data transfer speeds.
Least Queue Depth With Subset

The least queue depth with subset policy is also known as the least I/Os or least requests policy. This policy routes the next I/O request to a data path that has the least outstanding I/O requests queued. For this policy, an I/O request is simply a command in the queue. The type of command or the number of blocks that are associated with the command are not considered. The least queue depth with subset policy treats large block requests and small block requests equally. The data path selected is one of the paths in the path group of the RAID controller module that owns the virtual disk.

Least Path Weight With Subset

The least path weight with subset policy assigns a weight factor to each data path to a virtual disk. An I/O request is routed to the path with the lowest weight value to the RAID controller module that owns the virtual disk. If more than one data path to the virtual disk has the same weight value, the round robin with subset path selection policy is used to route I/O requests between the paths with the same weight value. The least path weight with subset load balance policy is not supported on Linux operating systems.

Load balancing with the MD3600i Series storage array is only available for Microsoft Windows Server 2008 and later versions of the operating system. You can change the load balance policies from the default round robin with subset by using either the:

- Device manager
- Disk management

To change the load balance policy using Windows Server 2008 device manager:

1. From the desktop of the host, right-click My Computer and select Manage to open the Computer Management dialog box.
2. Click Device Manager to show the list of devices attached to the host.
3. Right-click the multi-path disk device for which you want to set the load balance policies, then select Properties.
4. From the MPIO tab, select the load balance policy that you want to set for this disk device.
To change the load balance policy using Windows Server 2008 disk management:

1. From the desktop of the host, right-click My Computer and click Manage to open the Computer Management dialog box.
2. Click Disk Management to show the list of virtual disks attached to the host.
3. Right-click the virtual disk for which you want to set the load balance policy, then click Properties.
4. From the MPIO tab, select the load balance policy that you want to set for this virtual disk.

Increasing Bandwidth With Multiple iSCSI Sessions

The PowerVault MD3600i Series storage array in a duplex configuration supports two active/active asymmetric redundant controllers. Each controller has two 10G Ethernet ports that support iSCSI. The bandwidth of the two ports on the same controller can be aggregated to provide optimal performance. A host can be configured to simultaneously use the bandwidth of both the ports on a controller to access virtual disks owned by the controller. The multi-path failover driver that Dell provides for the MD3600i Series storage array can be used to configure the storage array so that all ports are used for simultaneous I/O access. If the multi-path driver detects multiple paths to the same virtual disk through the ports on the same controller, it load-balances I/O access from the host across all ports on the controller.

Figure C-1 illustrates how the initiator can be configured to take advantage of the load balancing capabilities of the multi-path failover driver.
Figure C-1. Initiator Configuration

IP Addresses
Host
If1: IP_Addr_If1
If2: IP_Addr_If2

MD36x0i Controller 0
P0: IP_Addr_C0_P0
P1: IP_Addr_C0_P1
MD36x0i Controller 1
P0: IP_Addr_C1_P0
P1: IP_Addr_C1_P1

TCP Connections
To MD36x0i Controller 0
T01: IP_Addr_If1 / IP_Addr_C0_P0
T02: IP_Addr_If2 / IP_Addr_C1_P1
To MD36x0i Controller 1
T11: IP_Addr_If1 / IP_Addr_C1_P0
T12: IP_Addr_If2 / IP_Addr_C1_P1

iSCSI Sessions
To MD36x0i Controller 0
Session 00: T01
Session 01: T02
To MD36x0i Controller 1
Session 10: T11
Session 11: T12
Two sessions with one TCP connection are configured from the host to each controller (one session per port), for a total of two sessions. The multi-path failover driver balances I/O access across the sessions to the ports on the same controller. In a duplex configuration, with virtual disks on each controller, creating sessions using each of the iSCSI data ports of both controllers increases bandwidth and provides load balancing.
Appendix—Using Internet Storage Naming Service

Internet Storage Naming Service (iSNS) server, supported only on Microsoft Windows iSCSI environments, eliminates the need to manually configure each individual storage array with a specific list of initiators and target IP addresses. Instead, iSNS automatically discovers, manages, and configures all iSCSI devices in your environment.

For more information on iSNS, including installation and configuration, see microsoft.com.
Appendix—Stopping iSCSI Services in Linux

Follow the procedure given below to manually stop the iSCSI services in Linux.

To shut down iSCSI services:

1. Stop all I/O.
2. Unmount all correlated file systems. Stop iSCSI services by running the following command:

   /etc/init.d/open-iscsi stop
